8 November 2026

Dear Editors of Knowledge and Information Systems,

Please consider our revised manuscript, "CPOR: Cumulative Protection for Online Reconciliation with Nodewise Error Limits," as a research article. CPOR characterizes the exact one-step protection set for nonnegative outcomes without a known upper bound. Updating remaining allowances from actual released errors maintains individual cumulative limits under aggregation constraints.

In response to the handling editor's request for recent comparisons, the paper includes the published same-task ProCAST learned-oblique method (AAAI 2026) and Aikawa et al.'s robust reconciliation (TMLR 2026). Li et al.'s preprint provides an additional same-task comparison on four applicable datasets. DUET (KDD 2025) now serves as a third main backbone, with PatchTST and DLinear, on all seven datasets and three training runs. The recent Biswas residual method and MCGrad regression extension (KDD 2026) retain their separate, clearly identified comparison scopes.

The primary experiments use common early/late windows and continuous 144-observation tests on every dataset. The continuous reset control changes only the midpoint allowance reset. The AEMO evaluation also retains an uninterrupted month on all three backbones.

The strongest operator comparison supplies identical Coherent PIR candidates to common shrinkage, two-group shrinkage and full projection. At equal protection, full projection reduces mean-node RMSE by 3.57% and 4.34% against common shrinkage, and by 2.72% and 3.28% against two-group shrinkage, in window and continuous tests respectively. Full projection of Coherent PIR is named Protected PIR throughout the paper. Cov and ML, under the same CPOR protection rule, improve on Protected PIR by 3.57%/3.58% in windows and 5.67%/5.59% continuously; M5 favors Protected PIR on every backbone. All protected paths meet the cumulative limits. These target-selection contrasts and the same-candidate publication contrasts are separate from complete-procedure accuracy: DUET-based Cov/ML remain less accurate than unprotected PIR on average. ECommerce reversals, system-level deterioration and protection costs are retained.

The submission includes clean main and supplementary PDFs, editable LaTeX sources and Online Resource 2 v11. The resource index maps current tables to unrounded records and checking commands while retaining the previous numerical archive. No experiments were added during this manuscript revision. AI assistance is disclosed in the manuscript.

Thank you for considering the submission.

Yours sincerely,
Lei Zhang
